reasons you should use the built-in software and not drivers for an H-61M-S1 motherboard. As it is widely used and developed, a display becomes a kind of indispensable consumer electronic product, which is widely applied in our daily life. A liquid crystal display (LCD) with good display effect is widely applied for the following mobile phones, tablet computers, digital cameras, notebook computers, TVs, display and the like. The liquid crystal display (LCD) is a common high resolution display device, and can display images by changing the intensity of transmitted light via light-conversion of liquid crystals. As a common type of the liquid crystal display (LCD), a twisted nematic liquid crystal display (TN LCD) is widely used at present. The operation principle of the liquid crystal display (LCD) mainly includes the following steps: 1. applying a voltage to a pixel electrode and a common electrode to form a potential field between the pixel electrode and the common electrode; and 2. arranging the liquid crystals under the potential field so that the liquid crystal molecules are twisted along the potential field. However, there is a deviation phenomenon for the liquid crystal, due to its bad response speed. A liquid crystal capacitor causes a slow transition and is difficult to handle. Thus, the size of the liquid crystal capacitor is required to be reduced to achieve the purpose of reducing the size of the display, and at the same time, to increase the response speed of the liquid crystal display (LCD). In order to achieve the purpose of reducing the size of the liquid crystal capacitor, the size of one liquid crystal capacitor is designed to be equal to the size of one pixel of a display panel, and the two glass substrates in the liquid crystal capacitor are aligned with each other with a gap, so as to form the liquid crystal capacitor, which is connected to a pixel electrode via a vertical gap. Although this structure has a small liquid crystal capacitor, it cannot achieve the

Field of the Invention This invention relates to a power-driven grinding machine for accurately finishing the interior of an aluminum casting by grinding the removal of flash from the surface of the casting. 2. Description of the Prior Art There is a great demand for high-strength aluminum alloys in aircraft, particularly in the engine cowl area. These materials require special finishing processes, not found in the usual flat-grinding processes, in order to

obtain a surface which is free of surface blemishes, i.e. surface imperfections such as pitting, holes, grooves, and the like. Aluminum alloys which contain magnesium and iron also require special finishing treatments to eliminate other surface blemishes or paint imperfections which would make the paint adhere poorly to the finished casting. The usual finish processes are electric-discharge or vibration-type, however, it is not possible to use these methods to finish aluminum alloys. In particular, it is not possible
